

- Echo vs print in php

In PHP, both echo and print are used to output content to the browser or standard output. However, there are a few differences between them:

1. Syntax: The syntax for echo is `echo expression;`, while the syntax for print is `print expression;` or `print(expression);`. Note that echo does not require parentheses, whereas print can optionally use parentheses.
2. Return Value: echo does not have a return value and can only output multiple expressions separated by commas. On the other hand, print returns a value of 1 and can only output a single expression.
3. Performance: echo is generally considered to be faster and more efficient than print because it is a language construct, while print is a function. However, the performance difference is usually negligible, and it's not a significant factor in most cases.
4. Usage: echo is more commonly used in PHP code due to its simplicity and wide adoption. It is often used to output HTML, text, or variables directly. print is less frequently used and is typically used when the return value is needed for a specific use case.
